## Executive Summary

---

Lawrence Livermore National Security, LLC operates facilities at Lawrence Livermore National Laboratory (LLNL) in which radionuclides are handled and stored. These facilities are subject to the U.S. Environmental Protection Agency (EPA) National Emission Standards for Hazardous Air Pollutants (NESHAPs) in Code of Federal Regulations (CFR) Title 40, Part 61, Subpart H, which regulates radionuclide emissions to air from Department of Energy (DOE) facilities. Specifically, NESHAPs limits the emission of radionuclides to the ambient air to levels resulting in an annual effective dose equivalent of 10 mrem (100  $\mu$ Sv) to any member of the public. Using measured and calculated emissions, and building-specific and common parameters, LLNL personnel applied the EPA-approved computer code, CAP88-PC, Version 4.0.1.17, to calculate the dose to the maximally exposed individual member of the public for the Livermore Site and Site 300.

In 2015, LLNL maintained its compliance with 40 CFR 61, Subpart H. All radioactive air emissions resulted in calculated doses far below the annual 10 mrem (100  $\mu$ Sv) site-wide standard. The annual doses to the site-wide maximally exposed individual member of the public at the Livermore Site and Site 300 from planned operations in 2015 are:

- Livermore Site:  $1.7 \times 10^{-3}$  mrem ( $1.7 \times 10^{-2}$   $\mu$ Sv)
- Site 300:  $4.8 \times 10^{-4}$  mrem ( $4.8 \times 10^{-3}$   $\mu$ Sv)

---

## Background Information

LLNL is a premier research laboratory that is part of the National Nuclear Security Administration (NNSA) within DOE. As a national security laboratory, LLNL is responsible for ensuring that the nation's nuclear weapons remain safe, secure, and reliable. The Laboratory also meets other national security needs, including countering the proliferation of weapons of mass destruction and strengthening homeland security, and conducts major research in atmospheric, earth, and energy sciences; bioscience and biotechnology; and engineering, basic science, and advanced technology. The Laboratory serves as a scientific resource to the U.S. government and a partner to industry and academia.

Because LLNL is a DOE facility, it is subject to the requirements of 40 CFR 61, Subpart H, National Emission Standards for Emissions of Radionuclides Other than Radon from Department of Energy Facilities. This regulation limits emissions of radionuclides to ambient air to levels resulting in an annual effective dose equivalent of 10 mrem (100  $\mu$ Sv) to any member of the public. The regulation also requires annual reporting of the emissions and resulting dose.

### 1.1 SITE DESCRIPTION

LLNL consists of two sites—an urban site in Livermore, California, referred to as the “Livermore Site;” and a rural experimental test site, referred to as “Site 300,” near Tracy, California (**Figure 1**).

**Figure 1.** Locations of LLNL's Livermore Site and Site 300.

The Livermore Site is just within the eastern city limits of Livermore, a city of about 85,000 in Alameda County. The site occupies 1.3 square miles, including the land that serves as a buffer zone around most of the site. Within a 50-mile radius of the Livermore Site are communities such as Tracy and Pleasanton and the more distant (and more densely populated) cities of Oakland, San Jose, and San Francisco. Of the 7.8 million people within 50 miles of the Laboratory, only about 10% are within 20 miles.

Site 300, LLNL's Experimental Test Site, is located in the Altamont Hills of the Diablo Range and straddles the San Joaquin and Alameda county line. The site is 12 miles east of the Livermore Site and occupies 10.9 square miles. The city of Tracy, with a population of about 86,000, is approximately 6 miles to the northeast (measured from the northeastern border of Site 300 to Sutter Tracy Community Hospital). Of the 7.1 million people who live within 50 miles of Site 300, 95% are more than 20 miles away in metropolitan areas such as Oakland, San Jose, and Stockton.

The weather conditions at the Livermore Site and Site 300 are very similar. The climate at both sites is best described as Mediterranean, characterized by mild, rainy winters and warm-to-hot, dry summers. However, the complex topography of Site 300 does influence local wind and temperature patterns. The stronger winds that occur at the higher elevations of Site 300 (**Figure 2**), results in warmer nights and slightly cooler days than the Livermore Site.

**Figure 2.** Wind roses for the Livermore Site and Site 300 for 2015.

The 2015 annual wind data for both sites are displayed as wind roses in **Figure 2**. In the wind rose, the length of each spoke is proportional to the frequency at which the wind blows from the indicated direction; different line widths of each spoke represent wind speed classes. These data show that for the Livermore Site, winds blew from the southwest through west about 43% of the time; for Site 300, the data show that the winds blew from the southwest to the west about 45% of the time. The average wind speed in 2015 at the Livermore Site was 2.2 m/s (4.9 mph), and the average wind speed at Site 300 was 5.6 m/s (12.5 mph). In 2015, the Livermore Site received 20.4 cm (8.0 in) of rain and Site 300 received 18.8 cm (7.4 in).

## 1.2 SOURCE DESCRIPTION

Many different radioisotopes were available for use at LLNL in 2015 for research purposes, including biomedical tracers, tritium, mixed fission products, transuranic isotopes, and others—see **Table 1**. Radioisotope handling procedures and work enclosures are determined for each project or activity, depending on the isotopes, the quantities being used, and the types of operations being performed. Work enclosures include glove boxes, exhaust hoods, and laboratory bench tops. Exhaust paths to the atmosphere include High Efficiency Particulate Air (HEPA) filtered ventilation systems, roof vents and stacks without abatement devices, resuspension of depleted uranium from soil due to wind conditions and previous open-air explosives testing at Site 300, and releases to ambient air from a variety of diffuse sources. **Table 2** identifies the buildings, by managing organization, at LLNL where there was a potential for release of radioactive materials to the air in 2015.

---

## Emissions Data

LLNL categorizes radionuclide emission sources into one of two categories; major sources or minor sources. Major sources are defined as those that have the potential to emit radionuclides that could result in an annual potential dose of 0.1 mrem (1  $\mu$ Sv) or more to a member of the public at an off-site location; the radionuclide NESHAPs regulation requires continuous monitoring where the annual potential dose is in excess of 0.1 mrem (1  $\mu$ Sv). Minor sources are defined as sources that do not have the potential to cause an annual dose of 0.1 mrem (1  $\mu$ Sv). At LLNL, all major sources of emissions are point sources, i.e., stack emission points; however, minor sources include both point sources and diffuse sources.

### 2.1 MAJOR SOURCES: MEASURED EMISSIONS

In 2015, there were five facilities at the Livermore Site and one facility at Site 300 that had radionuclide air effluent continuous monitoring systems. These facilities are listed in **Table 3**, along with the number of samplers, the types of samplers, and the analytes of interest. Some of these facilities have the potential to emit radionuclides that would cause an annual dose in excess of the 0.1 mrem (1  $\mu$ Sv) standard; these sources are major sources following the definition given above. Others have in the past had potential emissions that required monitoring, and the monitoring continues to be maintained to assure that any emissions are well characterized and that the potential effect on the public and the environment is well understood.

Many of the monitored stacks at LLNL have effluent controls, such as HEPA filters, to collect materials before they are emitted to the atmosphere. Air samples for particulate emissions are extracted downstream of HEPA filters and prior to the discharge point to the atmosphere. Particles are collected on high efficiency cellulose membrane filters. The sample filters are removed and analyzed for radioactive particulate activity on a weekly or bi-weekly frequency depending on the facility. In all cases, continuous passive filter aerosol collection systems are used. At some facilities, continuous air monitors (CAMs) also sample the stack air exhaust for radionuclides. CAMs have an alarm capability for the facility in the event of an unplanned release of alpha activity. CAMs are used for facility personnel safety; they are not used for NESHAPs compliance demonstration.

**Table 3.** Air effluent sampling systems and locations.

Building	Facility	Analytes	Sample type	Number of samplers
235	Building in Physical and Life Sciences Directorate	Gross $\alpha$ , $\beta$ on particles	Filter	1
331	Tritium Facility	Gaseous tritium/ tritiated water vapor	Ionization Chamber <sup>a</sup>	4
		Gaseous tritium/ tritiated water vapor	Glycol Bubblers	2
332	Plutonium Facility	Gross $\alpha$ , $\beta$ on particles	Filters	15
		Gross $\alpha$ , $\beta$ on particles	CAM <sup>a</sup>	12
581	National Ignition Facility	Gross $\alpha$ , $\beta$ , Gamma suite on particles	Filter	1
		Radioiodine (volatile)	TEDA cartridge	1
		Gaseous tritium/ tritiated water vapor	Glycol Bubbler	1
		Gaseous tritium/ tritiated water vapor	Ionization Chamber <sup>a</sup>	1
695/696	Decontamination and Waste Treatment Facility	Gross $\alpha$ , $\beta$ on particles	Filter	1
801A	Contained Firing Facility (Site 300)	Gross $\alpha$ , $\beta$ on particles	Filter	1

Note: "CAM" denotes continuous air monitors. "TEDA" denotes triethylenediamine.

<sup>a</sup> Alarmed systems used for notification for any unplanned release; they are not used for NESHAPs compliance demonstration.

Gas flow proportional counters and gamma spectroscopy are used to detect radioactive particulate activity collected on the filters. For verification of the operation of the counting system, calibration sources, and background samples are interspersed among the sample filters for analysis. The Radiological Measurements Laboratory (RML) in LLNL's Radiation Protection Functional Area and the Environmental Monitoring Radio-analytical Laboratory (EMRL) in the Physical and Life Sciences Directorate perform the analyses.

When the result for gross alpha or gross beta on a particulate filter is greater than the minimum detectable concentration (MDC), the filter is recounted. If the second result is also above the MDC, the filter is submitted to the EMRL for isotopic analysis to determine whether the activity on the filter is the result of naturally occurring radionuclides or is reportable as a radionuclide emission from the facility.

Glycol bubblers are used to monitor for tritium releases from the two Tritium Facility (Building 331) stacks, and the National Ignition Facility (NIF) stack. In addition to this NESHAPs compliance monitoring, the two Tritium Facility stacks, and the NIF stack are monitored using ion chambers. The ion chamber monitors are set to alarm at

designated tritium concentrations to identify accidental or off-normal releases. Ion chambers are in place for notification only so that any unplanned release may be detected; they are not used for NESHAPs compliance demonstration, but data may serve as supportive information. All of the stack samplers monitor continuously.

Because tritium can be released in the form of either tritiated water vapor (HTO) or gaseous tritium (HT), glycol bubblers employ a two-stage glycol impinging process to capture both physical forms. Stack air to be sampled enters the instrument and flows through the first stage impingers, capturing the HTO present. Next, the sampled air is directed through a heated palladium catalyst where oxidation of any HT in the sample takes place, converting gaseous tritium to HTO, which is then collected in the second stage impingers. The impingers are analyzed by the RML using liquid scintillation analysis. This type of sampling quantifies the amount of tritium for both species, HT and HTO.

Tritium in particulate form is monitored when required with the use of high efficiency (better than HEPA grade) cellulose membrane filters. Measurements to date indicate that tritium exchange (adsorption of tritium in HTO and/or HT captured in the filter medium via a binding reaction) occurs; this is verified by placing two particulate filters in series and comparing the results (applying 2-sigma error) on each filter. If tritiated particulate were present, then the pre-stream filter (the filter that comes into contact with stack air first) would have a higher amount of tritium than the post-stream filter (the filter that comes into contact with stack air immediately after the pre-stream filter). This is because the pre-stream filter would have significantly filtered out particles prior to the post-stream and would result in less tritium on the post-stream filter. The pre-stream filter and post-stream filter show the same amount of tritium (within analytical error) indicating tritium exchange.

Triethylenediamine (TEDA) cartridges are used to sample for radioactive iodines in gaseous or vapor state. The TEDA is impregnated into carbon (activating the carbon) by the manufacturer and is housed in a plastic cartridge of standard industry size 2 ¼" diameter by 1" thick (30 × 50 Mesh). Stack air is directed through the TEDA cartridge, which is the second stage of the two-stage filter housing. Both the particulate filter (first stage) and the TEDA cartridge (second stage) are counted by gamma spectroscopy by the EMRL.

In 2015, stack measurements indicate that a total of 43.7 Ci (1617 GBq) of tritium was released from the Tritium Facility. Of this, approximately 90% of tritium was released as HTO. The remaining 10% was HT.

The NIF released a total of 1.44 Ci (53.3 GBq) of measured tritium from the stack exhaust in 2015. Of this, approximately, 86% of tritium was released as HTO. The remaining 14% was HT.

The Contained Firing Facility at Site 300 had measured depleted uranium emissions in 2015 consisting of  $1.1 \times 10^{-7}$  Ci ( $4.1 \times 10^{-6}$  GBq) of uranium-234,  $9.5 \times 10^{-9}$  Ci ( $3.5 \times$

$10^{-7}$  GBq) of uranium-235, and  $7.3 \times 10^{-7}$  Ci ( $2.7 \times 10^{-5}$  GBq) of uranium-238 in particulate form.

None of the other facilities monitored for radionuclides had reportable emissions in 2015.

## 2.2 MINOR SOURCES: AMBIENT MEASUREMENT COMPARISON

With EPA's Region IX approval, LLNL demonstrates compliance for minor emissions sources (both non-monitored stack and area sources) through the use of ambient air monitoring data. The method entails comparing measured ambient air concentrations at the location of the site-wide maximally exposed individual (SW-MEI) to concentration limits set by EPA in its Table 2 of Appendix E to 40 CFR 61. The radionuclides for which the comparisons are made are tritium and plutonium 239+240 for the Livermore SW-MEI and uranium-238 for the Site 300 SW-MEI (see **Table 6** in Section 3.3.2).

## 2.3 MINOR SOURCES: SOURCE TERM ESTIMATE

To provide additional confirmation of the dose contributions from diffuse minor sources of tritium, LLNL estimated the source terms for these sources using a mathematical optimization routine that minimizes the root-mean-square (*rms*) differences between modeled and measured annual average ambient tritium concentrations (MacQueen et al. 2013; see **Figure 5** in Section 3.3.2 of this report for the ambient air sampling locations). This process has two parts.

First, CAP88-PC is used to model the contribution each source (both point and diffuse) makes to the annual average tritium concentration in HTO at each of the ambient air monitoring locations. Each point source is modeled using source-specific model parameters (activity, stack height, etc.). The diffuse sources are modeled using a unit source (1 Ci), a 1-meter height, a 10-meter diameter, and a fixed plume rise across stability classes A through F. All models use the same LLNL 2015 wind file. The individual contributions (both point and diffuse) at each monitoring location are added to produce an all-sources-combined model estimate of the annual average ambient concentration at each location.

Second, the 1 Ci source term for each diffuse source is adjusted independently using the mathematical search routine. The point sources are held fixed. The adjusted diffuse source terms that produce the best fit of the all-sources-combined model concentrations to the measured concentrations are then used to calculate the dose contribution from each diffuse source.

In 2015, the best-fit diffuse source term estimates were 1.14 Ci for the Building 331 Waste Accumulation Area (WAA), 0.09 Ci for Building 298 activities, 0.43 Ci for location OS 495 that is a programmatic WAA, and 0.57 Ci for the Building 581 WAA. The measured and best-fit model annual average ambient air concentrations are shown in **Figure 3**.

**Figure 3.** Comparison of measured and modeled annual average concentrations of tritiated water vapor (HTO) in units of pCi/m<sup>3</sup> in air at Livermore Site ambient air locations, 2015.

#### 2.4 MINOR SOURCES: OPEN-AIR TESTS

Another potential source of radioactive air emissions from LLNL operations at Site 300 is the emission of materials from open-air explosives tests. In 2015, there were no open-air explosives tests that contained radioactive materials.

## Dose Assessment

### 3.1 GENERAL

To comply with NESHAPs regulations and DOE guidance, the EPA-approved atmospheric dispersion and radiation dose calculation computer code, CAP88-PC, Version 4.0.1.17, was used to calculate the dose at specific distances from release points. For diffuse sources having a significant contribution to total dose, in addition to comparing the emissions to the concentration limits set by EPA in its Table 2 of Appendix E to 40 CFR 61, doses were calculated using either CAP88-PC or standard breathing rates and dose conversion factors.

For LLNL to comply with the NESHAPs regulations, the LLNL SW-MEI cannot receive an effective dose equivalent greater than 10 mrem/y (100  $\mu$ Sv/y). The SW-MEI is defined as the *hypothetical* member of the public at a single residence, school, business, church, or other such facility who receives the greatest LLNL- induced dose from the combination of all evaluated radionuclide source emissions, as determined by modeling. At the Livermore Site, the SW-MEI for 2015 was located at the LLNL Visitors Center (VIS) about 125 feet (38 m) outside the controlled eastern fence line of the site, but about 195 feet (59 m) within the perimeter of the site property. At Site 300, the 2015 SW-MEI was located at the boundary with the Carnegie State Vehicle Recreation Area, managed by the California Department of Parks and Recreation, approximately 1.9 miles (3.2 km) south-southeast of the firing table at Building 851. The locations of the SW-MEI's for both LLNL sites are shown in **Figure 4**.

**Figure 4.** Location of Site-Wide Maximally Exposed Individual (SW-MEI) at the Livermore Site and Site 300, 2015.

## 3.2 CAP88-PC INPUT PARAMETERS

Input parameters to CAP88-PC include the emissions discussed in Section 2, and building-specific and common parameters, discussed below. To estimate dose, CAP88-PC, Version 4.0.1.17, provides a library of the radionuclides at LLNL. In addition, when calculating dose from particulate alpha- and beta-emitting radionuclides, LLNL assigns gross alpha and gross beta measurements to the radionuclides handled in the facility when they can be specifically identified, or to plutonium-239+240 and strontium-90, respectively. The use of plutonium-239+240 and strontium-90 to represent alpha and beta emissions provides a health-conservative estimate of the dose.

### 3.2.1 Building-Specific Parameters

For dose assessment, LLNL uses building-specific information about radionuclide releases, as well as building-specific parameters for stack height, stack exhaust rate, stack diameter, and distances to the fence line. The building specific parameters are presented in **Attachment 1**.

### 3.2.2 Common Parameters

The input parameters that are common among LLNL sources are the agricultural parameters. Meteorological data from the LLNL Livermore Site meteorological tower are used to model Livermore Site sources, and meteorological data from the LLNL Site 300 meteorological tower are used to model Site 300 sources. Site-specific values for annual precipitation (8.0 in. [20.4 cm] for the Livermore Site and 7.4 in. [18.8 cm] for Site 300) and annual average ambient temperature (59.4°F [15.2°C] for the Livermore Site and 65.8°F [18.8°C] for Site 300) were used. The CAP88-PC default for absolute humidity of 8 grams per cubic meter was used, and is a reasonable representation of conditions at LLNL. The value for lid (mixing) height of 2,461 feet (750 m) was chosen for the Livermore Site, whereas the lid height value for Site 300 was 3,281 feet (1,000 m). The 2015 wind data are provided in **Attachment 2**.

For agricultural parameters in CAP88-PC, LLNL used area-weighted mean values based on data from the U.S. Department of Agriculture (USDA 2012) and the U.S. Census Bureau (USCB 2014) for periodic update. These were last updated in 2014.

County-specific agricultural data were obtained from the USDA sources. The borders of California counties were downloaded from the USCB website. For each county that intersects an 80 km radius circle around LLNL, the area of the overlapping portion of the county was calculated using geographic information system (GIS) software. Each of these areas was divided by the sum of the areas to determine the proportion of the 80 km radius circle representing each county. These proportions were then used to calculate the area weighted averages of the county-specific agricultural data. The results are shown in **Table 4**.

**Table 4.** Agricultural parameter values representing LLNL used in CAP88-PC.

Parameter	Value
Beef cattle density (# cows/km <sup>2</sup> )	4.02
Milk cattle density (# cows/km <sup>2</sup> )	13.16
Land fraction cultivated for vegetable crops	0.0021

For individual and collective doses from ingestion, it was assumed that 100% of milk is imported (i.e., free from LLNL-generated radioactivity), and that vegetables and meat are 25% home-grown and 75% imported.

### 3.2.3 Distances and Directions

In 2014, LLNL reviewed and updated its database of distances from sources to the fence-line and potential receptor locations using GIS and Google Earth software. Adjustments of up to about 15 meters were made to a few source locations. No further adjustments were made for 2015.

## 3.3 COMPLIANCE ASSESSMENT

### 3.3.1 Major Sources

Doses from LLNL's major sources, which are point sources, were evaluated using CAP88-PC and the input parameters discussed above. The modeled doses to the SW-MEI for the facilities where there were measured emissions are shown in **Table 5**. The specific results for all sources are provided in **Attachment 1**.

**Table 5.** Monitored point source doses for 2015.

Facility	Dose (mrem)
Tritium Facility (B331)	$1.4 \times 10^{-3}$
NIF (B581)	$1.2 \times 10^{-5}$
CFF (B801A)	$1.3 \times 10^{-7}$

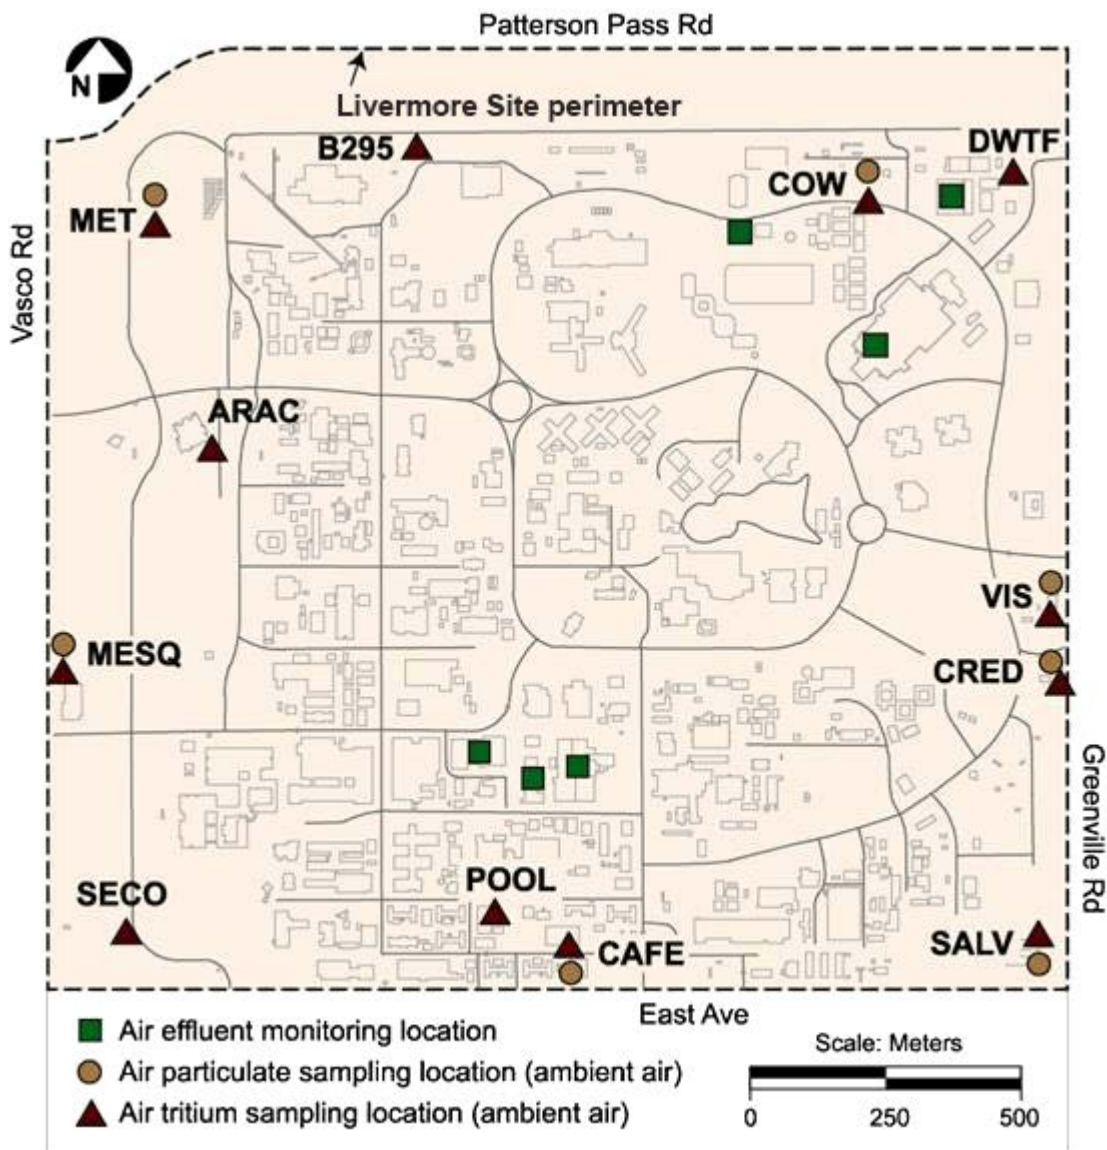

### 3.3.2 Minor Sources

LLNL has many minor sources; most of them are point sources and a few are diffuse. As stated previously, with EPA's Region IX approval, LLNL demonstrates compliance for minor emissions sources (both diffuse and non-monitored stack sources) through the comparison of ambient air monitoring data with concentration limits set by EPA in Table 2 of Appendix E to 40 CFR 61. This is done for tritium and plutonium-239+240 for the Livermore SW-MEI and uranium-238 for the Site 300 SW-MEI.

The 2015 average monitoring results for tritium and plutonium from the sampling location at the Livermore Site SW-MEI (VIS) were used for the purposes of this minor source comparison. (See **Figure 5** for a map of all Livermore Site sampling locations). The results of these comparisons are shown in **Table 6**. In 2015, there was one plutonium-

239+240 result above the detection limit at the VIS location. The remaining plutonium-239+240 samples for 2015 were below the detection limit.

At Site 300, wind-driven re-suspension of soil contaminated with depleted uranium is of potential interest in the minor source category. From 2008 to 2014, but in contrast to previous years, no ambient measurements for uranium showed a contribution from depleted uranium at the SW-MEI (see **Figure 4** for the location of the Site 300 SW-MEI). In 2015, there were two air samples that had a depleted uranium signature of approximately 18%. The remaining 82% of the uranium in the samples is from naturally occurring uranium. The mean of the two depleted uranium signature samples are shown in **Table 6**.

**Figure 5.** Radiological air monitoring locations at the Livermore Site.

The measured concentrations at the SW-MEI are presented in **Table 6**. Also shown in **Table 6** are EPA's standards from Table 2 of Appendix E to 40 CFR 61. As demonstrated by the calculation of the fraction of the standard, LLNL's measured concentrations in air for tritium, plutonium-239+240, and uranium-238 are all less than 0.003 (0.3%) of the standard for these radionuclides.

**Table 6.** Mean concentrations of radionuclides of concern at the location of the SW-MEI in 2015 compared to EPA's concentration standard.

Location	Nuclide	EPA's Table 2 concentration standard	Mean measured concentration	Measured concentration as a fraction of the standard	Detection limit
Livermore Site SW-MEI	Tritium	$1.5 \times 10^{-9}$ Ci/m <sup>3</sup>	$1.5 \times 10^{-12}$ Ci/m <sup>3a</sup>	$1.0 \times 10^{-3}$	$1 \times 10^{-12}$ Ci/m <sup>3</sup>
Livermore Site SW-MEI	Plutonium-239	$2.0 \times 10^{-15}$ Ci/m <sup>3</sup>	$3.2 \times 10^{-20}$ Ci/m <sup>3b</sup>	$1.6 \times 10^{-5}$	$5 \times 10^{-19}$ Ci/m <sup>3</sup>
Site 300 SW-MEI	Uranium-238	$8.3 \times 10^{-15}$ Ci/m <sup>3</sup>	$2.5 \times 10^{-18}$ Ci/m <sup>3c</sup>	$3.0 \times 10^{-4}$	$3 \times 10^{-20}$ Ci/m <sup>3</sup>

<sup>a</sup> The measured tritium value includes contributions from all major and minor sources including stack and diffuse releases measured at the location of the SW-MEI.

<sup>b</sup> There was one Pu-239 detection at the location of the Livermore SW-MEI in 2015 from resuspended previously contaminated soil.

<sup>c</sup> Based on the two samples that had a depleted uranium signature at the location of the Site 300 SW-MEI in 2015 from resuspended previously contaminated soil.

The source terms for the diffuse sources of tritium were developed as described in Section 2.3, and the doses were calculated using CAP88-PC. The total diffuse source dose for 2015 at the SW-MEI was  $3.3 \times 10^{-4}$  mrem ( $3.3 \times 10^{-3}$  μSv) for the Livermore Site. The diffuse dose at the SW-MEI at Site 300 from resuspended depleted uranium was  $4.8 \times 10^{-4}$  mrem ( $4.8 \times 10^{-3}$  μSv). **Attachment 1** lists the doses from diffuse sources.

### 3.3.3 SW-MEI Dose

Doses from LLNL's airborne emissions are well below the 10 mrem (100 μSv) NESHAPs annual dose standard. The annual doses (point source plus diffuse source) to the hypothetical SW-MEI at the Livermore Site and at Site 300 are:

- Livermore Site:  $1.7 \times 10^{-3}$  mrem ( $1.7 \times 10^{-2}$  μSv)
- Site 300:  $4.8 \times 10^{-4}$  mrem ( $4.8 \times 10^{-3}$  μSv)

The EPA-approved software calculates the dose assuming a person resides there all year for 24 hours a day, and eats meat and vegetables grown at the location (see agricultural parameters in Section 3.2.2). Thus, the calculated dose to this hypothetical person, the SW-MEI, is greater than the dose to an actual resident.

**Table 7** presents 2015 doses with those of previous years. Diffuse source doses were not reported for the Livermore Site for 1990 and 1991 and were not reported for Site 300 for 1990 through 1992.

**Table 7.** Doses (in mrem) calculated for the Site-Wide Maximally Exposed Individual (SW-MEI) for the Livermore site and Site 300, 1990 to 2015.

Year	Total Dose	Point Source Dose	Diffuse Source Dose

1991	0.044	0.044	— <sup>d</sup>
1990	0.057	0.057	— <sup>d</sup>

<sup>a</sup> The dose includes HT emissions modeled as HTO. Modeling HT emissions as such results in an overestimation of the dose. This methodology is used for purposes of compliance, as directed by EPA Region IX. Beginning in CY13, the EPA NESHAPs compliance modeling code CAP88-PC Version 4.0.1.17 now allows tritium to be modeled in both species, HT and HTO.

<sup>b</sup> Point and diffuse source doses were not reported separately from the total dose for the Livermore Site for 1990 and 1991.

<sup>c</sup> Diffuse emissions dose was not calculated because ambient monitoring did not yield SW-MEI results indicating the presence of depleted uranium. This is primarily due to no atmospheric shots with DU since 2008, and not significant amounts of contaminated soil disturbance.

<sup>d</sup> No diffuse emissions were evaluated at Site 300 for years before 1993.

---

## Certification

I certify under penalty of law that this document and all attachments were prepared under my direction or supervision in accordance with a system designed to assure that qualified personnel properly gather and evaluate the information submitted. Based on my inquiry of the person or persons who manage the system, or those persons directly responsible for gathering the information, the information submitted is, to the best of my knowledge and belief, true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment for knowing violations.

**Name:** Frances Alston, Ph.D.  
Director  
Environment, Safety & Health  
Lawrence Livermore National Laboratory  
7000 East Avenue, L-510  
Livermore, CA 94551

**Signature:** Frances Alston Date: 6/15/16  
Frances Alston

I certify under penalty of law that I have personally examined and am familiar with the information submitted herein, and based on my inquiry of those individuals immediately responsible for obtaining the information, I believe that the submitted information is true, accurate, and complete. I am aware that there are significant penalties for submitting false information, including the possibility of fine and imprisonment. See 18 U.S.C. 1001.

## Additional Information

### 5.1 UNPLANNED RELEASES

There were no unplanned releases in 2015.

---

## Supplemental Information

### 6.1 COLLECTIVE DOSE ASSESSMENT

Collective population dose is calculated using CAP88-PC as the average radiation dose to a person in a specified area, multiplied by the number of people in that area. In accordance with DOE and EPA guidance documents, all radionuclides potentially emitted in 2015 were assumed to be released from a central location. The total population within 50 miles (80 km) of the Livermore Site is approximately 7.8 million, and the total population within 50 miles (80 km) of Site 300 is approximately 7,1 million. The populations were derived using Oak Ridge National Laboratory LandScan 2010 data and ESRI ARCMAP software. The population file is provided in Attachment 3. The estimated collective dose attributable to LLNL airborne emissions in 2015 to persons living within 50 miles (80 km) of the Livermore Site is 0.13 person-rem (0.0013 person-Sv) and to persons living within 50 miles (80 km) of Site 300 is  $2.4 \times 10^{-5}$  person-rem ( $2.4 \times 10^{-7}$  person-Sv).

### 6.2 40 CFR 61 SUBPARTS Q AND T

LLNL does not have storage and disposal facilities for radium containing materials that would be a significant source of radon. LLNL does not have or store any uranium mill tailings.

### 6.3 PERIODIC CONFIRMATORY MEASUREMENT

Results of NESHAPs periodic confirmatory measurements (PCM) are intended to support or confirm two objectives: 1) that those operations not continuously monitored do not, in fact, need to be continuously monitored and 2) that radionuclide usage-inventory-based estimates of emissions and their corresponding doses are conservative.

For sources evaluated to have a potential to result in a dose less than the regulatory value of 0.1 mrem/y that requires continuous monitoring under Subpart H, LLNL achieves the PCM objectives by fulfilling the requirements stated in 40 CFR 61.93, paragraph (e) with its ambient air monitoring program. The ambient air monitoring effort includes more than 30 sampling locations with more than 40 samplers placed in strategic areas (see the Air Monitoring Programs section in the LLNL Site Annual Environmental Report [<https://saer.llnl.gov/>] for a description of LLNL's ambient air radiological monitoring).

### 6.4 FACILITY COMPLIANCE

In 2015, LLNL maintained its compliance with 40 CFR 61 Subpart H. All emissions resulted in calculated doses well below the 10 mrem (100  $\mu$ Sv) standard.

**Attachment 1** provides the dose estimates for each individual source.

<sup>a</sup> Gross alpha and Gross beta emissions are continuously monitored at the stack.																	
<sup>b</sup> Because monitoring takes place after abatement, an unabated EDE cannot be determined from the monitoring data (see discussion in Section 2, Emissions Data).																	
<sup>c</sup> Stack emissions have been combined as permitted by the EPA/DOE Memorandum of Understanding.																	
<sup>d</sup> Tritium HT and HTO emissions from the stack are continuously monitored.																	
<sup>e</sup> Air emissions are continuously sampled at the post-HEPA-filter atmospheric discharge points, although potential emissions are low enough that stack monitoring is not required per the NESHAPs 40 CFR 61 regulations.																	
<sup>f</sup> Gamma Emissions are continuously monitored at the stack																	
<sup>g</sup> Radioiodines are continuously monitored at the stack																	
<sup>h</sup> The unabated EDE shown is only for the tritium source term.																	
<sup>i</sup> Continuous monitoring for radioactive particulate is in place at surveillance locations																	
<sup>j</sup> Continuous monitoring for tritium is in place at surveillance locations																	

## ATTACHMENT 2: METEOROLOGICAL DATA

CAP88-PC requires meteorological data in the form of joint-frequency distributions of wind direction and wind speed organized by stability category. The first line of the file contains three hexadecimal file marks that are ignored by CAP88-PC. The second line is the average wind speed and is not used by CAP88-PC. The third line contains the wind frequency totals (in format 6.4, i.e., 6 places per value, 4 after the decimal place) beginning at the direction, N, and cycling counterclockwise through the wind directions. The following 8 lines contain the reciprocal average (or harmonic average) wind speed (in format 5.3) for each class of wind direction and stability. Each row is a stability class, A through G, and each "column" is the wind direction, again beginning at N and cycling counterclockwise. The next 8 lines are the arithmetic average wind speeds, in the same format as the reciprocal average. The final 16 lines are the frequencies of stability class, with the columns being the stability class and the rows the wind direction, beginning with N and cycling counterclockwise. The wind file for the Livermore Site was created from 2015 data collected from the Livermore Site meteorological tower at the 10-m level; the wind file for Site 300 was created from 2015 data collected from the Site 300 meteorological tower at the 10-m level.

### ATTACHMENT 3: POPULATION DATA

The source of the geographic population distribution data used for this report is Oak Ridge National Laboratory (ORNL) LandScan™ 2010 data and ESRI ARCMAP software. The data are placed into an annular grid that is created from sixteen 22.5-degree sectors centered on the cardinal wind directions and five distances spaced at 16 km to a total 80-km radius. In deriving the population for each site, the ORNL data set is input into ESRI ARCMAP with the 80-km grid for the Livermore Site centered at 37.686 N latitude, -121.7045 W longitude (near the center of the site) and Site 300 centered at the 52-m meteorological tower located at 37.675 N latitude, -121.541 W longitude. The first line of the input file is informational. Distances are shown in the second row. Population data begin in the third row starting with direction, N. There are 20 spaces reserved for each direction no matter how many are used; i.e., the next direction, NNW, starts approximately half-way through the fifth row, 21 values after the first value.

## ATTACHMENT 4: UNITS OF MEASURE AND EQUIVALENTS

### Symbols and Units of Measure

Bq	becquerel	mph	mile per hour
GBq	gigabecquerel (10 <sup>9</sup> Bq)	mrem	millirem (10 <sup>-3</sup> rem)
°C	degree centigrade	m/s	meter per second
Ci	curie	mrem/y	millirem per year (10 <sup>-3</sup> rem/y)
cm	centimeter	pCi	picocurie (10 <sup>-12</sup> Ci)
°F	degree Fahrenheit	pCi/m <sup>3</sup>	picocurie (10 <sup>-12</sup> Ci) per meter cubed
in.	inch	person-Sv	person-sievert
km	kilometer	Sv	sievert
m	meter	μSv	microsievert
mi	mile	μSv/y	microsievert per year

### Metric and U.S. Customary Unit Equivalents

Category	From metric unit to U.S. customary equivalent unit		From U.S. customary unit to metric equivalent unit	
	Metric	U.S.	U.S.	Metric
Length	1 centimeter (cm)	0.39 inches (in.)	1 inch (in.)	2.54 centimeters (cm)
	1 millimeter (mm)	0.039 inches (in.)		25.4 millimeters (mm)
	1 meter (m)	3.28 feet (ft)	1 foot (ft)	0.3048 meters (m)
		1.09 yards (yd)	1 yard (yd)	0.9144 meters (m)
	1 kilometer (km)	0.62 miles (mi)	1 mile (mi)	1.6093 kilometers (km)
Volume	1 liter (L)	0.26 gallons (gal)	1 gallon (gal)	3.7853 liters (L)
		8.11 × 10 <sup>-7</sup> acre-feet	1 acre-foot	1.23 × 10 <sup>6</sup> liters (L)
	1 cubic meter (m <sup>3</sup> )	35.32 cubic feet (ft <sup>3</sup> )	1 cubic foot (ft <sup>3</sup> )	0.028 cubic meters (m <sup>3</sup> )
		1.35 cubic yards (yd <sup>3</sup> )	1 cubic yard (yd <sup>3</sup> )	0.765 cubic meters (m <sup>3</sup> )
Weight	1 gram (g)	0.035 ounces (oz)	1 ounce (oz)	28.6 gram (g)
	1 kilogram (kg)	2.21 pounds (lb)	1 pound (lb)	0.454 kilograms (kg)
	1 metric ton (MT)	1.10 short ton (2000 pounds)	1 short ton (2000 pounds)	0.90718 metric ton (MT)
Area	1 hectare (ha)	2.47 acres	1 acre	0.40 hectares (ha)
Radioactivity	1 becquerel (Bq)	2.7 × 10 <sup>-11</sup> curie (Ci)	1 curie (Ci)	3.7 × 10 <sup>10</sup> becquerel (Bq)
Radiation dose	1 gray (Gy)	100 rad	1 rad	0.01 gray (Gy)
Radiation dose equivalent	1 sievert (Sv)	100 rem	1 rem	0.01 sievert (Sv)
Temperature	°Fahrenheit = (°Centigrade × 1.8) + 32		°Centigrade = (°Fahrenheit - 32) / 1.8
